## Connectivity analysis – issues and how to's

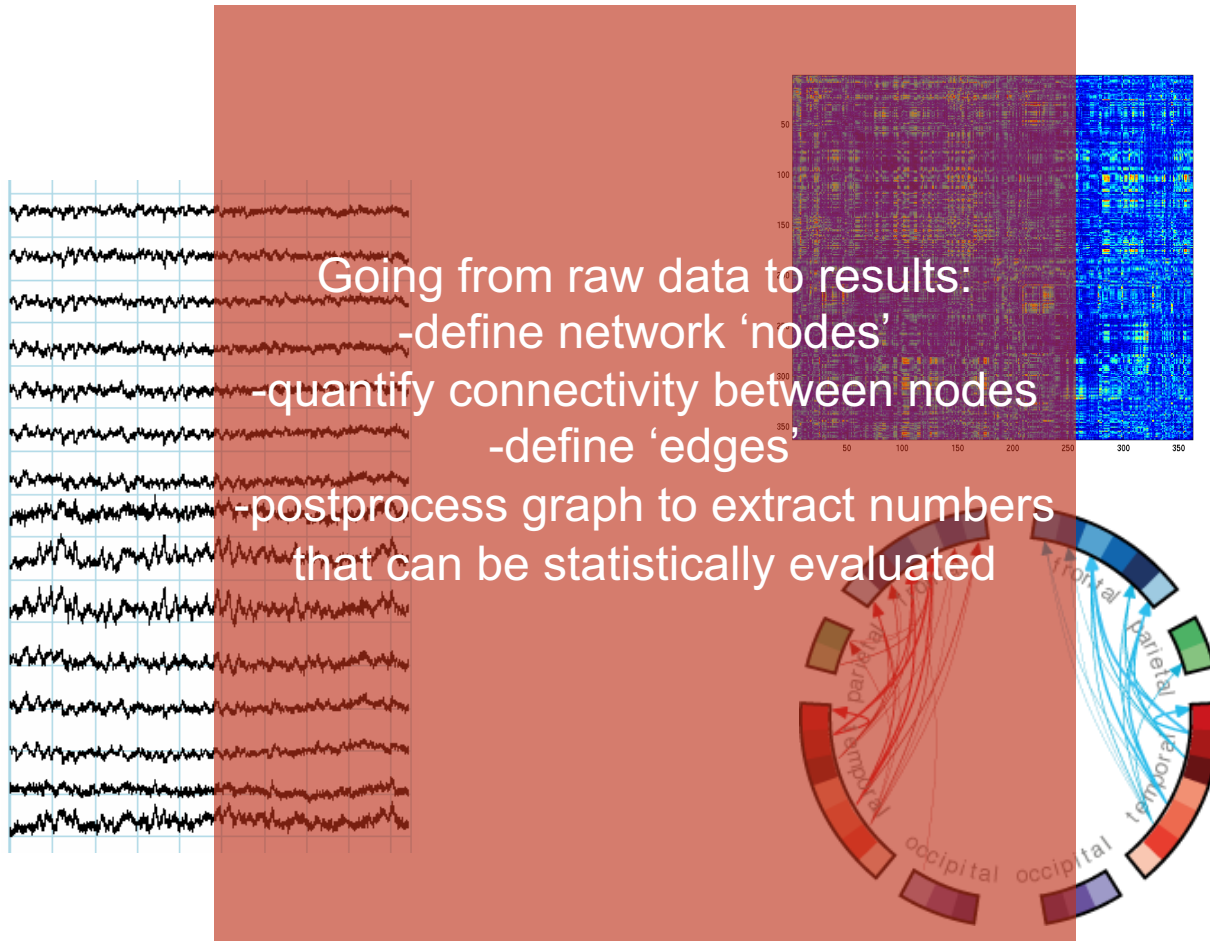

### From EEG/MEG data to results

Connectivity analysis – issues and how to's

## From EEG/MEG data to results

Connectivity analysis – issues and how to's

## From EEG/MEG data to results

1. Definition of network nodes: channels versus sources
2. Definition of connectivity
3. Definition of edges:
  - Few vs. many: seed-based
  - ROI vs. ROI
  - Many vs. many
4. Statistical evaluation (possibly after extraction of graph theoretic quantities)

## Connectivity analysis – issues and how to's

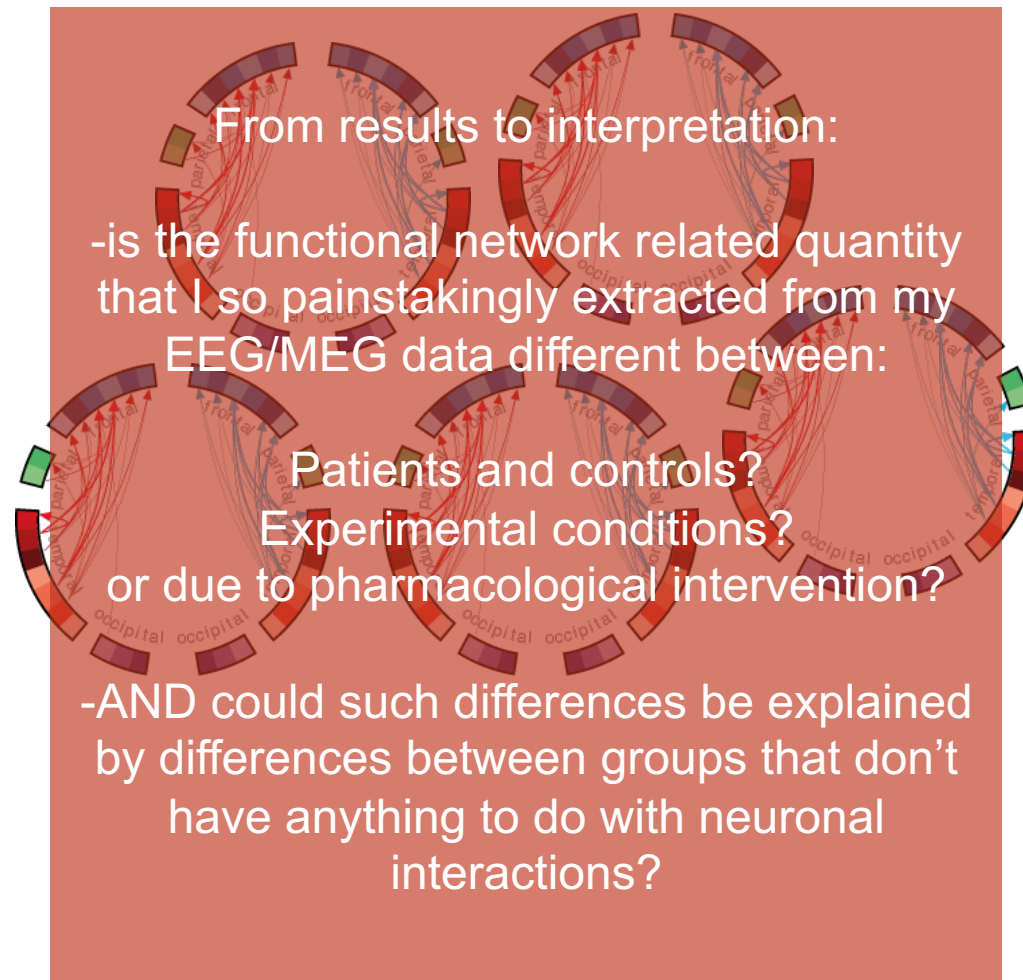

### From results to interpretation

## Connectivity analysis – issues and how to's

### From results to interpretation

## Take home messages

- Always keep in mind what is measured with M/EEG
- Interpret your results with care

- Don't forget what is measured with M/EEG
  - Don't over-interpret your results

## Connectivity analysis – issues and how to's

### Generation of M/EEG signals: synchronized post-synaptic potentials

Connectivity analysis – issues and how to's

Generation of M/EEG signals:  
primary currents lead to volume  
currents

## Connectivity analysis – issues and how to's

Generation of M/EEG signals:  
signals represent an  
instantaneous unknown mixture  
of underlying neuronal sources

Connectivity analysis – issues and how to's

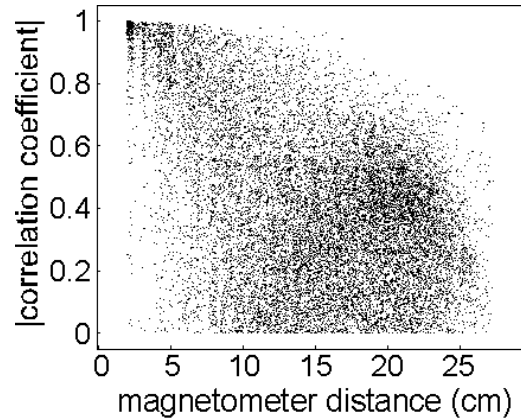

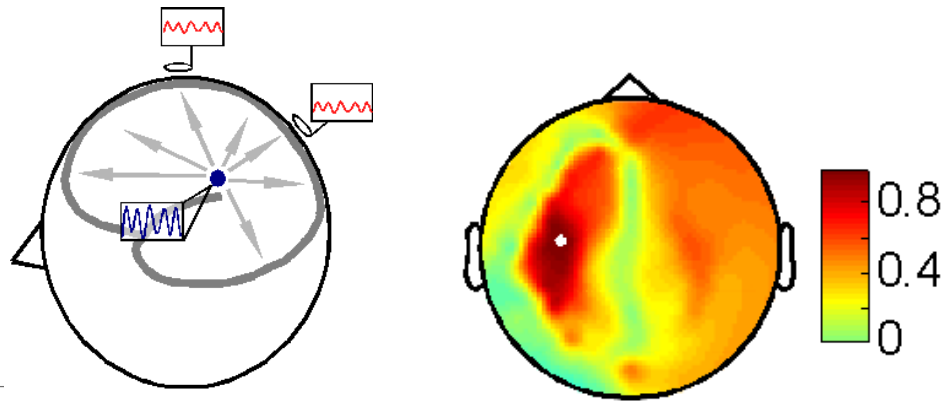

Quantification and interpretation of networks at channel level does not really make sense.

- No unambiguous relationship between network nodes and anatomical regions.
- Instantaneous mixing leads to mis-estimation (typically spurious) of connectivity

## Connectivity analysis – issues and how to's

Quantification and interpretation of networks at channel level does not really make sense.

## Address the issue of spurious estimates due to instantaneous mixing

- Use a connectivity measure that ‘discards’ the instantaneous contribution to the interaction estimate (e.g.: imaginary part of coherency, (weighted) phase lag index, orthogonalized amplitude envelope correlations).
- Do the network analysis at the level of the reconstructed sources

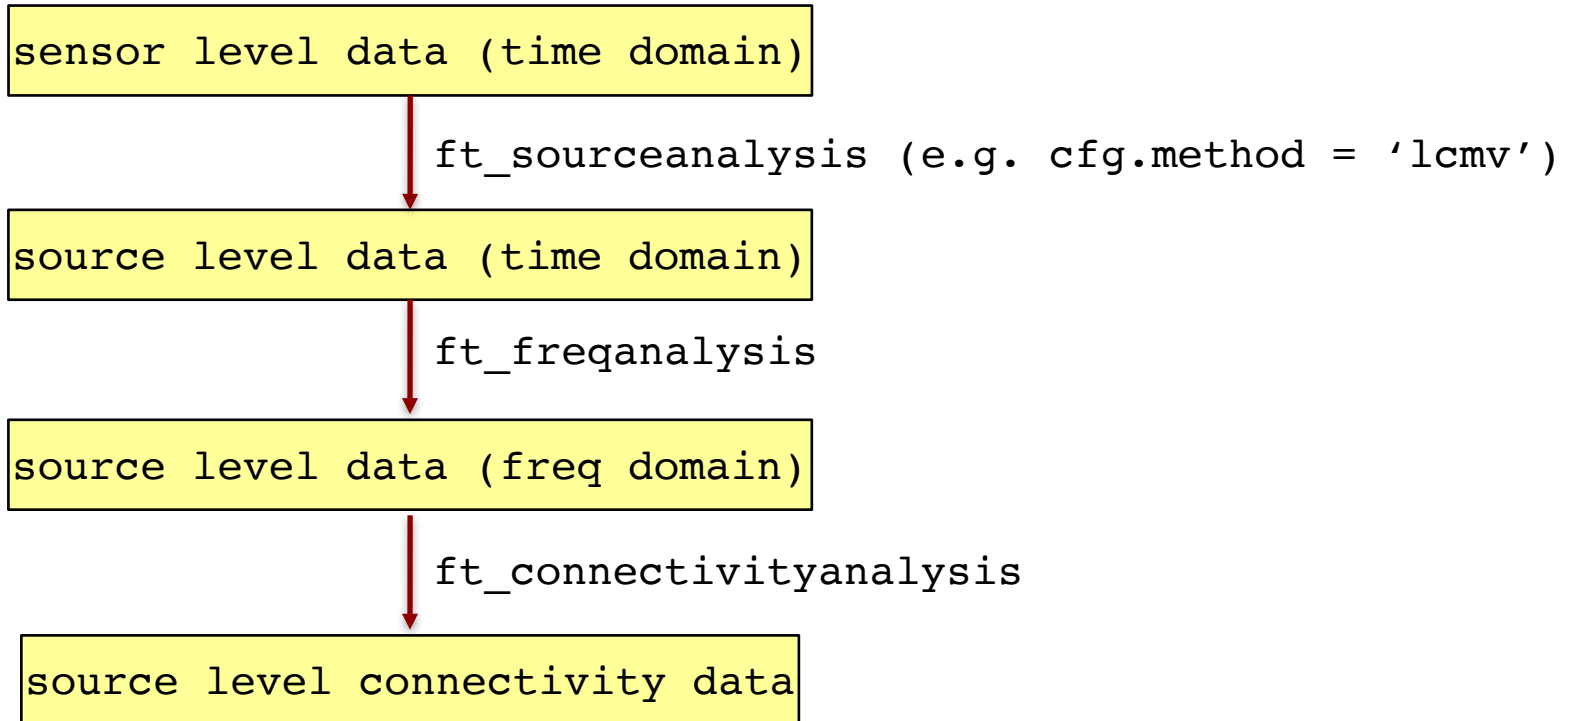

## Source reconstruction prior to connectivity estimation

- ‘Unmix’ the instantaneous mixing.
- Adds a level of complexity to the analysis
- Limits meaningful interpretable connectivity studies to recordings with large number of electrodes
- Unmixing is never perfect: spatial leakage of activity
- Define spatial ‘granularity’ in source space

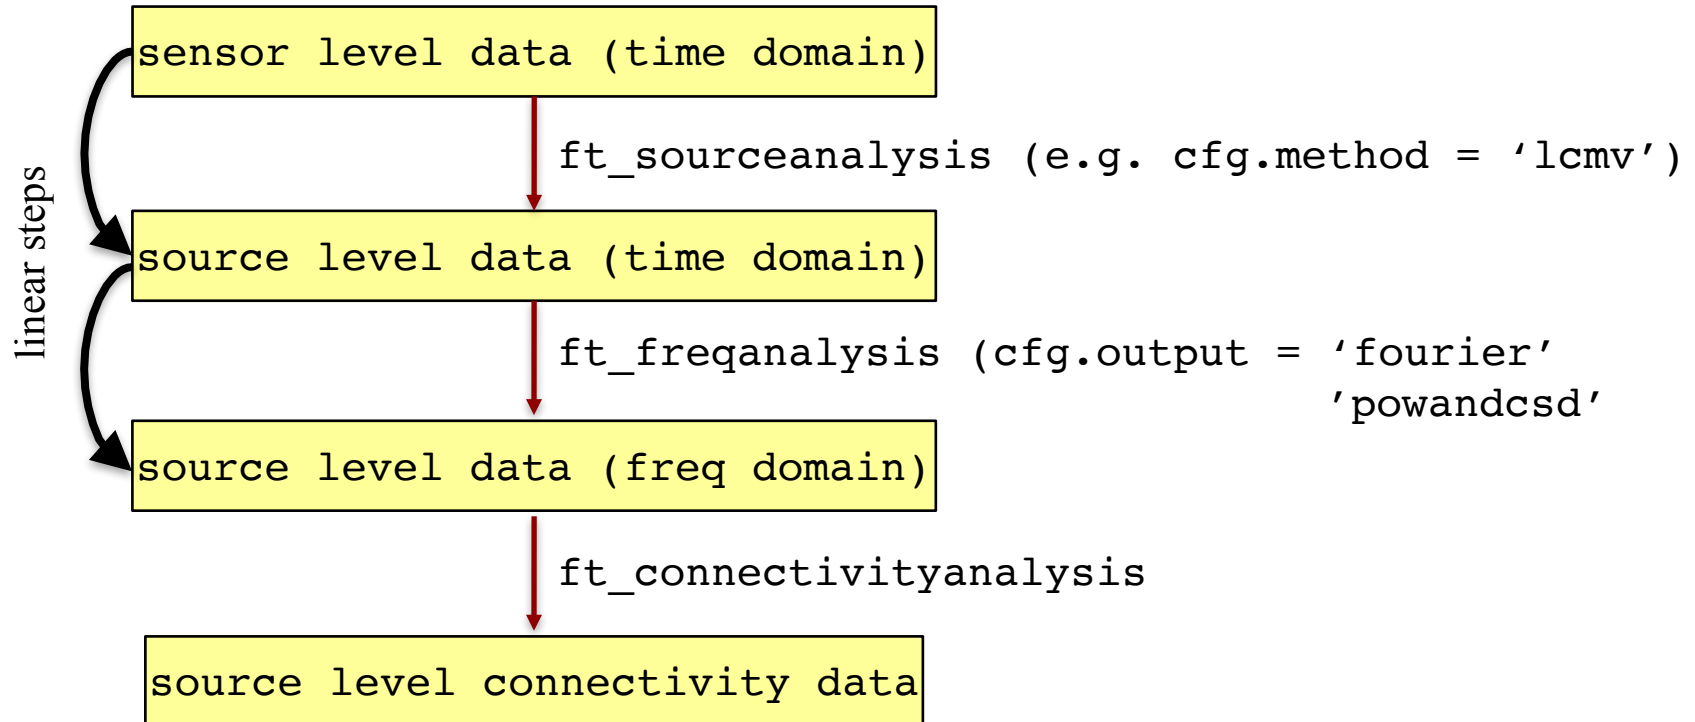

## Analysis recipe

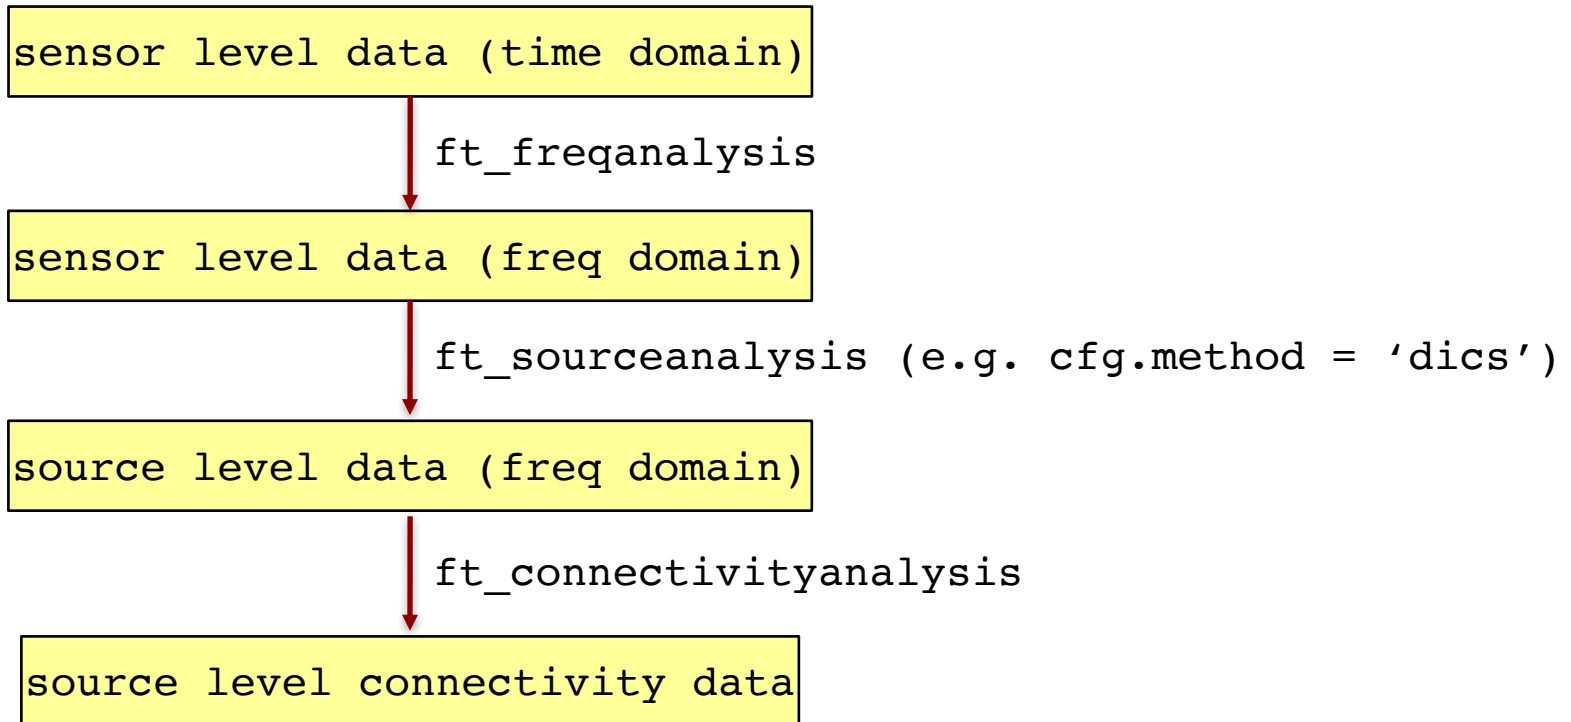

## Analysis recipe

## Analysis recipe (revised)

## Ft\_sourceanalysis how to's

```
% get spatial filter, common across conditions
% (assuming there's more than one condition
cfg                = [];
cfg.method         = 'dics';
cfg.headmodel     = headmodel;
cfg.grid          = sourcemodel;
cfg.dics.keepfilter = 'yes';
source = ft_sourceanalysis(cfg, freqall);
```

```
% use computed spatial filter to get single
% condition data
cfg                = [];
cfg.method         = 'dics';
cfg.headmodel     = headmodel;
cfg.grid.filter    = source.avg.filter;
cfg.dics.keepfilter = 'no';
source1 = ft_sourceanalysis(cfg, freq1);
source2 = ft_sourceanalysis(cfg, freq2);
```

If there is only a single condition, e.g. resting state, or when single trial data are needed

```
% get spatial filter
```

```
cfg = [];  
cfg.method = 'dics';  
cfg.headmodel = headmodel;  
cfg.grid = sourcemodel;  
cfg.dics.keepfilter = 'yes';  
source = ft_sourceanalysis(cfg, freqall);
```

```
% use computed spatial filter to get single  
% trial data
```

```
cfg = [];  
cfg.method = 'dics';  
cfg.headmodel = headmodel;  
cfg.grid.filter = source.avg.filter;  
cfg.dics.keepfilter = 'no';  
cfg.rawtrial = 'yes';  
source1 = ft_sourceanalysis(cfg, freq1);  
source2 = ft_sourceanalysis(cfg, freq2);
```

Connectivity analysis – issues and how to's

## More efficient: use 'pcc' as method

```
% get spatial filter + source-level fourier data in a single fast
% fast call to ft_sourceanalysis
cfg                                = [];
cfg.method                        = 'pcc';
cfg.headmodel                    = headmodel;
cfg.grid                          = sourcemodel;
cfg.pcc.keepfilter               = 'yes';
source = ft_sourceanalysis(cfg, freqall);

% note, optimal benefit only when freq-domain channel data is
% computed as follows
freqall = ft_freqanalysis(cfg, data); % with cfg.output = 'fourier';

% then, the single trial (taper) data is in the following data field
>> source.avg

ans =
      csd: {Nx1 cell}
      mom: {Nx1 cell} % per dipole location fourier coefficients
  csdlabel: {Nx1 cell}
```

## Spatial leakage at the source level warrants careful interpretation

True source activity

Estimated source activity

## Spatial leakage at the source level warrants careful interpretation

True source connectivity

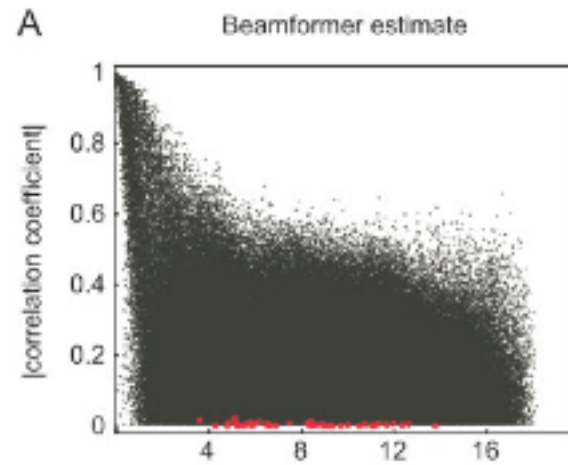

Estimated source conn

## Connectivity analysis – issues and how to's

### Spatial leakage at the source level warrants careful interpretation

## Connectivity analysis – issues and how to's

### Spatial granularity

- Acknowledge spatial noise in the connectivity maps
- Pool across dipole locations to increase SNR
  - Spatial resolution is relatively low
  - From a generative model point of view: regional sources rather than dipoles
- Strategy: use 'parcellation' scheme to go from 5000x5000 to 250x250 edges
- Parcellation also relevant when adding time / frequency dimensions to connectivity maps (data reduction)

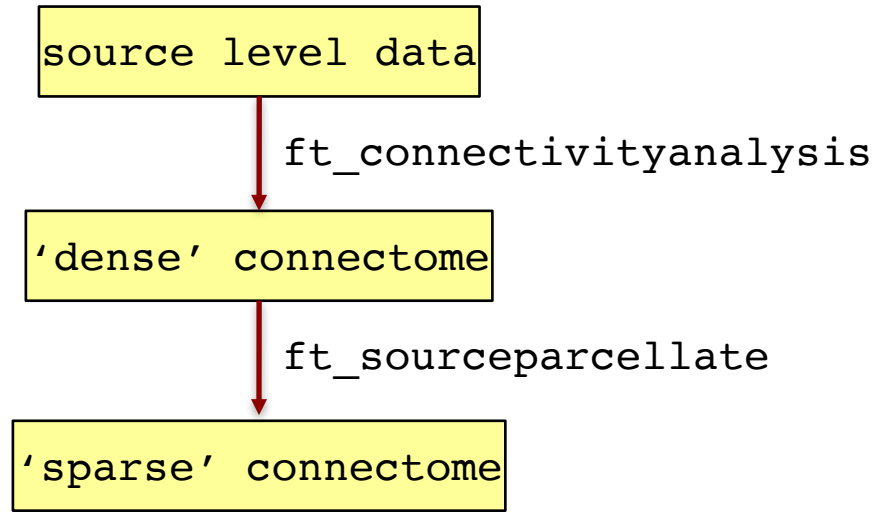

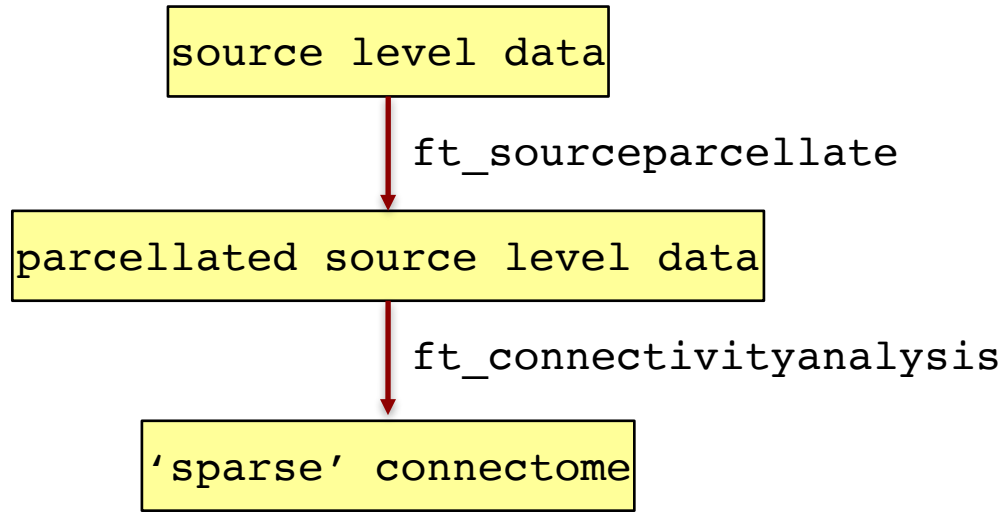

## Connectivity analysis – issues and how to's

### Analysis recipe parcellation

## Analysis recipe parcellation

```
source_parcc =
```

```
    label: {Mx1 cell}  
    cohspctrm: [MxM double]  
    cohspctrmdimord: 'chan_chan'  
    cfg: [1x1 struct]
```

## Statistical evaluation (group level)

- Unlike `ft_freqstatistics/ft_timelockstatistics`, FT does not have a '`ft_connectivitystatistics`'.
- Yet, working with parcellated data, in which each parcel is represented as a channel, allows for the use of `ft_freqstatistics`
- Interpretation: report on condition/group differences in power
- If possible: account for condition/group differences in power
